ABERRATION OF 4-AND 3-LOOP-MONITORS

by

R. Rossmannith

ABSTRACT

The aberrations of several loop-monitors for measuring the displacement of an electron-beam in an accelerator are calculated. The picture produced by induced signal of an orthogonal lattice in a plan perpendicular to beam direction is distorted similar to distortion by optical lenses. The distortion can be reduced by using 8-Loop-instead of 4-Loop-Monitors.

INTRODUCTION

Usually pick-up electrodes or loop-monitors are used to detect the position of the electron beam in an accelerator relative to the ideal beam center line. With loop-monitors the magnetic field of the beam induces a signal to the loop, with pick-up electrodes on the contrary the electric field of the beam interacts with the electric field of the monitor. Though special formed pick-up electrodes with linear response are known¹ the sensitivity is small compared with loop-monitors. Two different 4-loop-configurations are used^{2,3} (fig. 1 and 2).

³ Bergere, R., Veyssiere, A. and Doujat, P.: Rev. Sci. Instr. 33 (1962) pp. 1441 - 1449

In figure 1 the horizontal and vertical displacement is detected by measuring the difference of the induced signals:

$$R_{\text{HOR},1} = A - B \quad (A, B, C, D: \text{induced signals to the loops } a, b, c, d) \quad (1)$$

$$R_{\text{VERT},1} = C - D$$

In figure 2 the measured displacement is:

$$R_{\text{HOR},2} = E + F - G - H \quad (E, F, G, H: \text{induced signals to the loops } e, f, g, h) \quad (2)$$

$$R_{\text{VERT},2} = E + G - F - H$$

As shown later, both configurations give distorted response. With a 8-loop-monitor, that is a combination of both 4-loop-monitors, one expects a reduction of distortion because the distortion of configuration fig. 1 is negative, the distortion of fig. 2 on the contrary is positive.

The horizontal and vertical response is given by summarizing the responses of the 4 loop-monitors:

$$\begin{aligned} R_{\text{HOR},3} &= A + E + F - B - G - H \\ R_{\text{VERT},3} &= C + E + G - D - F - H \end{aligned} \quad (3)$$

CALCULATION OF THE LOOP-RESPONSE:

For calculation of the induced signal to a loop the electron beam is assumed to have small expansion compared with the distance to the loop. The induction of a current to a parallel wire of length l is well known:

$$\frac{L^{1/2}}{A} = 2l \log \frac{l + \sqrt{r^2 + l^2}}{r} - 2 \sqrt{r^2 + l^2} + 2r \quad (4)$$

- A constant
- l length of the loop
- r distance between electron-beam and loop

The distance between the electron beam and the loops can be derivated from fig. 3

$$\begin{aligned} r_1 &= ((x^2 + y^2)^{1/2} + 2(x^2 + y^2)^{1/2} R \sin(\arctan(\frac{y}{x}) + \psi) + R^2)^{1/2} \\ r_2 &= ((x^2 + y^2)^{1/2} - 2(x^2 + y^2)^{1/2} R \sin(\arctan(\frac{y}{x}) + \psi) + R^2)^{1/2} \\ r_3 &= ((x^2 + y^2)^{1/2} - 2(x^2 + y^2)^{1/2} R \cos(\arctan(\frac{y}{x}) + \psi) + R^2)^{1/2} \\ r_4 &= ((x^2 + y^2)^{1/2} + 2(x^2 + y^2)^{1/2} R \cos(\arctan(\frac{y}{x}) + \psi) + R^2)^{1/2} \end{aligned} \quad (5)$$

- x, y coordinates of the beam
- R dinstance between geometrical center and loops
- ψ angle between vertical-axis and loop-axis.
In loop configuration fig. 1 ψ is zero and in fig. 2 ψ is $\pi/4$.

Combining the equations (4) and (5) the response for each configuration can be calculated. A rectangular lattice is constructed in the x-y plane (fig. 4). The distortion of the loop response of the lattice is demonstrated in fig. 5, 6 and 7. The indices of l and R refer to the loop-configurations of fig. 1. and 2. In table I the distortion of the different

loop-configurations are compared. As to be seen from fig. 7 the lattice distances increase with increasing distances from the axis. This deviation is shown in fig. 8.
