Received 26 February 1976

From measurements of the reaction  $ep \rightarrow e\pi^- \Delta^{++}$  near threshold the nucleon axial-vector form factor is determined, using the PCAC calculations by Adler and Weisberger. The results are consistent with form factor determinations from single pion electroproduction. A dipole fit yields  $m_A = (1.18 \pm 0.07)$  GeV.

The  $Q^2$  dependence of the nucleon axial vector form factor  $g_A(Q^2)$  has been determined in two essentially different ways. Direct determination is made from quasielastic  $\nu N$  scattering. Assuming the dipole form

$$g_A(Q^2) = g_A(0) (1 + Q^2/m_A^2)^{-2}$$

for the axial form factor the combined neutrino measurements give  $m_A = (0.89 \pm 0.08)$  GeV<sup>†1</sup>. An alternative, more indirect determination is made from  $\pi^+$  electroproduction

$$ep \rightarrow e'\pi^+n \quad (1)$$

near threshold, assuming the validity of current algebra and of the PCAC hypothesis. Measurements of this reaction at various laboratories [2–5] have recently lead to rather consistent results; the values of  $m_A$  obtained from them are between 1.00 and 1.14 GeV,

depending on the model used for the dependence on the pion mass.

A difficulty occurs in using reaction (1) to determine  $g_A(Q^2)$  due to the strong background from the resonant  $\pi^+n$  P-wave, which tends to mask the  $g_A(Q^2)$  dependent term even close to threshold. This problem is absent in the reaction

$$ep \rightarrow e'\pi^- \Delta^{++} (1236). \quad (2)$$

Here, the  $g_A(Q^2)$  dependent equal time commutator term given by current algebra is the *dominant* term in a range of at least several 100 MeV above threshold. Adler and Weisberger have derived and thoroughly discussed the low-energy theorem [6] to be used in the determination of  $g_A(Q^2)$  from measurements of reaction (2).

We have measured the dependence of reaction (2) on  $Q^2 = -(k_e - k'_e)^2$  using the DESY streamer chamber in conjunction with counter hodoscopes and proportional chambers to detect and identify all four particles in the final state, including the  $\pi^+$  and p from  $\Delta^{++}$  decay. The event sample used in the present analysis is twice as large as that used in a previous publication [7]. The cross section for reaction (2) was determined by maximum likelihood fits to the Dalitz plot of the hadronic  $\pi^+\pi^-p$  final state, taking into account distributions appropriate for  $\pi^- \Delta^{++}$ ,  $\pi^+ \Delta^0$ ,  $\rho^0 p$ , and phase

<sup>4</sup> Now at CERN, Geneva.

<sup>†1</sup> The determination in ref. [1] assumes CVC, smallness of the induced pseudoscalar term, and absence of second class currents. Relaxing the CVC requirement and so attempting to measure both  $m_A$  and  $m_V$  from the ANL neutrino experiment gives  $m_A = 0.75^{+0.21}_{-0.10}$  and  $m_V = 0.92^{+0.05}_{-0.11}$  GeV.

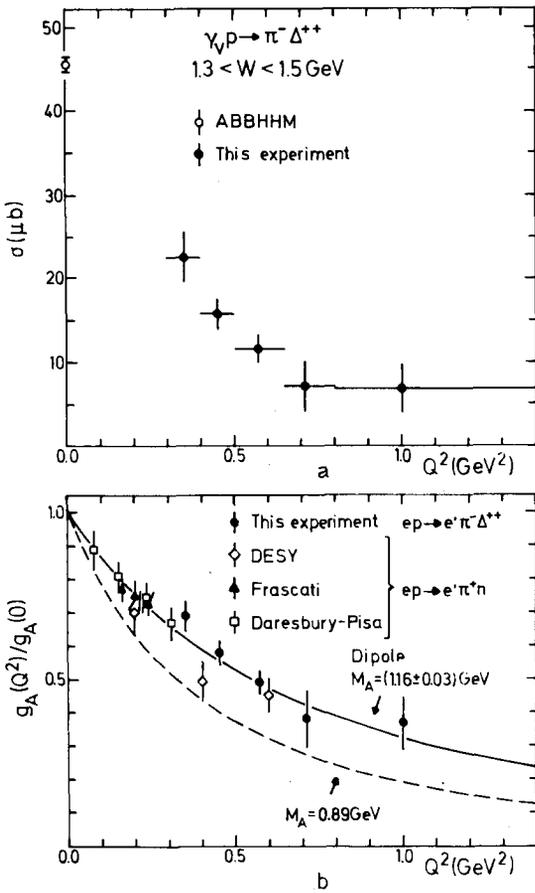

Fig. 1a). Cross section  $\sigma_{T_2^+} + \epsilon\sigma_L$  of the reaction  $\gamma_V P \rightarrow \pi^- \Delta^{++}$  for  $1.3 < W < 1.5 \text{ GeV}$ , as function of  $Q^2$ . The point at  $Q^2 = 0$  is taken from ref. [11]. The  $Q^2 > 0$  points have, in addition to the statistical errors shown, an overall uncertainty of 10%. b) Nucleon axial vector form factor as determined from the single pion electroproduction reaction (1) [2-4] and  $\pi\Delta$  electroproduction (reaction (2), this experiment). The solid curve shows a fit of the form  $(1 + Q^2/m_A^2)^{-2}$  to the electroproduction points. The broken curve shows the dipole form factor obtained from quasielastic neutrino scattering [1].

space. Corrections of typically 4% and 18% have been made for measurement inefficiencies and radiative effects, respectively (see ref. [8] for details).

The cross section for reaction (2), as a function of the total final state hadron mass  $W$ , rises approximately linearly from threshold up to  $W \approx 1.5 \text{ GeV}$  [7, 8]. This is consistent with the expected strong dominance of the equal time commutator term or, in Born term terminology, of the contact (plus some pion exchange)

term [6]<sup>#2</sup>. The dominance of the commutator term is further supported by our observed  $\Delta^{++}$  production and decay angular distributions. The  $Q^2$  dependence of the cross section in this region,  $1.3 < W < 1.5 \text{ GeV}$ , is shown in fig. 1a (after dividing out the  $Q^2$  dependent flux  $\Gamma_1$  of transverse virtual photons, defined in the conventional way [10]. The point at  $Q^2 = 0$  comes from photoproduction [11].

We now compare this  $Q^2$  dependence with the calculations by Adler and Weisberger [6], assuming PCAC. We have evaluated their expressions, valid in the exact soft pion limit ( $q_\pi = 0$ ), for the  $\pi^- \Delta^{++}$  final state. The cross section is very closely proportional to  $g_A^2(Q^2)$ , due to the strong dominance of the equal time commutator term. We refer to the calculated cross section, with  $g_A(Q^2)$  set equal to 1, as  $\sigma_{AW}(Q^2)$ .

In order to compare it with our measured  $Q^2$  dependence, the latter has to be extrapolated into the unphysical region at  $q_\pi = 0$ . The analysis which we have presented earlier [7] suggests a simple procedure to do this. In ref. [7] it was shown that the matrix element of the reaction

$$\gamma_V P \rightarrow \pi^- \Delta^{++} \quad (3)$$

is to good approximation given by the Born contact (seagull) amplitude multiplied with a phenomenological form factor  $G(Q^2)$ ,

$$\langle \Delta^{++} \pi^- | J_\mu | p \rangle \epsilon^\mu = G(Q^2) \bar{u}_\mu(\Delta) u(p) \epsilon^\mu. \quad (4)$$

In the physical region for  $W < 1.5 \text{ GeV}$  this matrix element describes very well the  $q_\pi$ ,  $Q^2$  and polarization dependence of the data. Thus our experimental data can be represented by

$$\frac{\sigma(Q^2)}{\sigma(0)} = G^2(Q^2) \frac{\sigma_{\text{BORN}}(Q^2, q_\pi \text{ physical})}{\sigma_{\text{BORN}}(0, q_\pi \text{ physical})}. \quad (5)$$

Assuming this relation to hold also between  $q_\pi$  at threshold and  $q_\pi = 0$ , we have

$$\frac{\sigma(Q^2, q_\pi \rightarrow 0)}{\sigma(0, q_\pi \rightarrow 0)} = G^2(Q^2) \frac{\sigma_{\text{BORN}}(Q^2, q_\pi \rightarrow 0)}{\sigma_{\text{BORN}}(0, q_\pi \rightarrow 0)} \quad (6)$$

where  $\sigma(Q^2, q_\pi \rightarrow 0)$  is the extrapolated cross section which can be directly compared with  $\sigma_{AW}(Q^2)$ :

<sup>#2</sup> Pole term models of  $\pi\Delta$  electroproduction have been discussed by Berends and Gastmans, by Bartl et al., and more recently in the framework of saturated fixed- $t$  dispersion relations by Levi and Schmidt [9].

$$\frac{\sigma(Q^2, q_\pi \rightarrow 0)}{\sigma(0, q_\pi \rightarrow 0)} = \frac{g_A^2(Q^2)}{g_A^2(0)} \frac{\sigma_{AW}(Q^2)}{\sigma_{AW}(0)}. \quad (7)$$

From this we determine  $g_A^2(Q^2)/g_A^2(0)$ .

Our results are shown in fig. 1b. A fit by a dipole formula to our data<sup>†3</sup> gives

$$m_A = (1.18 \pm 0.07) \text{ GeV}.$$

For comparison fig. 1b also shows form factor values obtained from single-pion electroproduction experiments [2–4] (reaction 1). We have plotted here values extracted from single  $\pi^+$  electroproduction using the model of Dombey and Read [12]. This model uses the Born approximation with pseudovector  $\pi N$  coupling where  $g_A(Q^2)$  occurs as a factor in the contact term. Thus, it resembles the approximation we are using in interpreting our  $\pi\Delta$  data. The resulting values for  $g_A(Q^2)$  from the two reactions are seen to be consistent; a dipole fit to the combined electroproduction data (including ours) gives  $m_A = (1.16 \pm 0.03) \text{ GeV}$ . A possible discrepancy with the value  $m_A = (0.89 \pm 0.08) \text{ GeV}$  obtained from neutrino scattering is indicated (broken curve).

Regarding the comparison with single-pion electroproduction however, there are other current algebra-based models for *single*  $\pi^+$  electroproduction which tend to lead to somewhat smaller values for  $g_A(Q^2)$ . Thus, in refs. [2] and [3] results for  $g_A(Q^2)$  were also extracted using the models of Furlan et al. [13] and of Benfatto et al. [14]; dipole fits to these results yield  $m_A = (1.00 \pm 0.03) \text{ GeV}$  and  $(1.02 \pm 0.04) \text{ GeV}$  for the

two models, respectively. These latter values are in reasonable agreement both with the results from neutrino reactions and with our results.

We thank Dr. H. Kowalski for useful comments. The work at Hamburg has been supported by the Bundesministerium für Forschung und Technologie, the work at Glasgow by the Science Research Council.
