Abstract. We investigate the sensitivity of Higgs(-like) inflation to higher dimensional operators in the nonminimal couplings and in the potential, both in the metric and Palatini formalisms. We find that, while inflationary predictions are relatively stable against the higher dimensional operators around the attractor point in the metric formalism, they are extremely sensitive in the Palatini one: for the latter, inflationary predictions are spoiled by $|\xi_4| \gtrsim 10^{-6}$ in the nonminimal couplings $(\xi_2\phi^2 + \xi_4\phi^4 + \dots) R$, or by $|\lambda_6| \gtrsim 10^{-16}$ in the Jordan-frame potential $\lambda_4\phi^4 + \lambda_6\phi^6 + \dots$ (both in Planck units). This extreme sensitivity results from the absence of attractor in the Palatini formalism. Our study underscores the challenge of realizing inflationary models with the nonminimal coupling in the Palatini formalism.

1 Introduction

The inflationary paradigm [1–3] is one of the fundamental elements of modern cosmology, providing an elegant solution to the horizon and flatness problems [3] and the dilution of possible unwanted relics [2]. Furthermore, the slow-roll inflation [4–6] successfully produces the primordial density perturbations by quantum fluctuations of the inflaton field [7, 8]. The inflation has become precision science, in which a few parameters of the model beautifully fits hundreds of data points in the observational data [9]. We expect further experimental improvements in near future, with the tensor-to-scalar ratio r being explored by the LiteBIRD [10], POLARBEAR-2 [11], and CORE [12] down to $r \sim 10^{-3}$.¹

The Higgs field is the only elementary scalar field in the Standard Model (SM) of particle physics, and it is tempting to consider a possibility that it plays the role of the inflaton field [15–18]. In these early studies, the possibility of induced gravity has been mainly pursued where the Einstein-Hilbert action S_{EH} is absent, and the nonminimal coupling ξ_2 between the Higgs field and the Ricci scalar is required to be of order $\xi_2 \sim 10^{34}$.² The modern version of the Higgs inflation [21] allows S_{EH} , which is not prohibited by any symmetry, and

¹The observation of r is important as it will be an indirect evidence of the quantum graviton fluctuation during the inflation, namely the first evidence of quantum gravity. Even direct observation of the cosmic graviton background might be possible in the future space interferometers such as the (Ultimate) DECIGO experiment [13, 14].

²See also refs. [19, 20] for inflation with the nonminimal coupling.

the nonminimal coupling becomes of order $\xi_2 \sim 10^{5-6}$.³ This modern version is indeed one of the best fit models of the current observational data [9].⁴ There are also variations in addition to this vanilla model: the critical [24, 26–28], the hill-climbing [29, 30], and the hill-top [31] Higgs inflations. Sharing the virtue of the vanilla model, these variations predict different values of r along with other observables such as $dn_s/d\ln k$, $d^2n_s/d\ln k^2$ as well as n_t , $dn_t/d\ln k$, which can possibly be used to distinguish between these models in near-future experiments.

However, such various Higgs inflations have been studied mainly in the so-called metric formalism for past decades. It is known that, even in the Einstein gravity, there are two different ways to formulate gravity: metric and Palatini formalisms.⁵ The former assumes the Levi-Civita connection from the beginning by imposing the metricity and torsion free conditions, while the latter regards the metric and connection as independent variables, with respect to which we take the variation of the action.⁶ Though these two formalisms give the same dynamics within the Einstein gravity, their predictions differ once we introduce nontrivial couplings with matter and gravity. This indeed happens in the Higgs inflation, and their difference has been attracting considerable interest recently [31, 35–51].

One may worry about the theoretical issues arising in the Palatini formalism, namely, strong coupling and uniqueness, which are pointed out in ref. [65] for $f(R)$ theories. However, we found that such issues do not directly apply to Palatini formalism in the case of Higgs inflation, in contrast to $f(R)$ theories (see appendix B).

In this paper, we study the (vanilla) Higgs inflation both in metric and Palatini formalisms. From the viewpoint of effective theory, the nonminimal coupling in the Higgs inflation $\xi_2\phi^2 R$ should be regarded as a truncation in the infinite series $(1 + \xi_2\phi^2 + \xi_4\phi^4 + \dots)R$. The potential term $\lambda_4\phi^4$ should also be regarded as a truncation in $\lambda_4\phi^4 + \lambda_6\phi^6 + \dots$. While there are extensive discussion on the scale at which these higher-order couplings appear [52–56],⁷ we at least expect that new physics effects appear at the Planck scale M_P . Therefore, if the inflationary predictions significantly depend on the higher-order terms suppressed by the Planck scale, it means that the model construction is challenging in such setups. This is indeed what we find for the Higgs inflation with the Palatini formalism.

³This possibility has also been commented in the earlier ref. [15] with essentially the same parameters: $\xi_2 \sim 10^4$ and the Higgs quartic coupling (around the Planck scale) $\lambda_4 \sim (\xi_2/10^5)^2 \sim 10^{-2}$.

⁴We note that the value of the running Higgs quartic coupling λ_4 has to be positive near the Planck scale for the successful Higgs inflation (see e.g. refs. [22, 23] for an uncertainty due to the lack of our knowledge of the ultraviolet completion), requiring the pole mass of the top quark to be $m_t^{\text{pole}} \lesssim 171.3 \text{ GeV}$ (see e.g. ref. [24]). The frequently quoted constraint $m_t^{\text{MC}} = 173.0 \pm 0.4 \text{ GeV}$ [25] is on the Monte Carlo mass, a parameter in the Monte Carlo code, whose relation to the pole mass is unknown. Currently the pole mass is best deduced from the cross-section measurements, and a simple combination of experiments gives $m_t^{\text{pole}} = 173.1 \pm 0.9 \text{ GeV}$ [25], which is 2σ -consistent with the Higgs inflation. Note that this bound may be too stringent since it assumes totally uncorrelated systematic errors among experiments. We also note that the inclusion of the Higgs-portal dark matter greatly relaxes the constraint even under the existence of the right-handed neutrinos [26].

⁵It has been noted [32] that the original Palatini’s paper [33] ‘was rather far from what is usually meant by “Palatini’s method,” which was instead formulated... by Einstein’ [34]. Here we follow the convention and call it Palatini anyway.

⁶Throughout this paper we assume vanishing torsion. In stringy context, this corresponds to assuming the trivial background for any higher-rank gauge fields. We note that while a three-form gauge-field background can be treated as a torsion, five- and higher-form gauge-field background cannot.

⁷Note that the cutoff-scale issue has turned out to be more severe at the preheating regime in the metric formalism [57] compared with earlier estimations [58–60]. This is due to explosive production of the longitudinal gauge bosons (see also ref. [61]). On the other hand, such an effect is reported to be absent in the Palatini formalism [62].

The organization of the paper is as follows. In section 2 we first introduce basic ingredients and review the inflationary predictions in the standard setup. In section 3, we investigate the sensitivity of the Higgs-like inflation to the higher-order corrections in the Weyl rescaling factor. In section 4, we investigate the sensitivity to the potential. Finally, we give summary and discussion in section 5. In appendix A, we show the full expressions for the relevant formulae.

2 Setup

In this section, we summarize two independent formalisms of Higgs-like inflation, namely the metric and Palatini formalisms, and review the standard predictions without higher order corrections for each case.

2.1 Basic ingredients: metric and Palatini formalisms

We start from the action in the Jordan frame:

$$S = \int d^4x \sqrt{-g_J} \left[\frac{1}{2} \Omega^2(\phi) g_J^{\mu\nu} R_{J\mu\nu} - \frac{1}{2} g_J^{\mu\nu} \partial_\mu \phi \partial_\nu \phi - V_J(\phi) \right], \quad (2.1)$$

where ϕ is the (Jordan-frame) inflaton and

$$\Omega^2(\phi) = 1 + \xi_2 \phi^2 + \xi_4 \phi^4 + \dots, \quad V_J(\phi) = \lambda_4 \phi^4 + \lambda_6 \phi^6 + \dots, \quad (2.2)$$

are the Weyl-rescaling factor and the Jordan-frame potential, respectively; here we have assumed the Z_2 symmetry: $\phi \rightarrow -\phi$.⁸ The Ricci tensor is $R_{J\mu\nu} = R_{J\mu\nu}(g_J)$ in the metric formalism while $R_{J\mu\nu} = R_{J\mu\nu}(\Gamma_J)$ in the Palatini formalism, with the arguments g_J and Γ_J symbolically denoting the metric and connection in the Jordan frame, respectively. The subscript J refers to the Jordan frame. We use the Planck unit $M_P = 1$ throughout the paper, with $M_P \equiv 1/\sqrt{8\pi G} = 2.4 \times 10^{18}$ GeV being the reduced Planck mass.

A metric redefinition by a Weyl transformation $g_{\mu\nu} = \Omega^2 g_{J\mu\nu}$ gives the transformation of the Ricci scalar as

$$R_J = \begin{cases} \Omega^2 \left[R + 3\Box \ln \Omega^2 - \frac{3}{2} (\partial \ln \Omega^2)^2 \right] & \text{(metric),} \\ \Omega^2 R(\Gamma) & \text{(Palatini),} \end{cases} \quad (2.3)$$

where the result for the Palatini formalism is trivially obtained as the Ricci tensor is independent of the metric transformation. After this, we obtain the Einstein-frame action

$$S = \int d^4x \sqrt{-g} \left[\frac{1}{2} g^{\mu\nu} R_{\mu\nu} - \frac{1}{2} (\partial\chi)^2 - V(\phi) \right], \quad (2.4)$$

⁸For the Higgs field, this is a natural assumption since the gauge invariance allows only a pair $H^\dagger H$ as a basic building block. If we relax this condition, there are other potentially interesting cases without the Z_2 symmetry such as $\Omega^2 = 1 + \xi_2 \phi^2 + \xi_3 \phi^3$ and $V_J = \lambda_4 \phi^4 + \lambda_6 \phi^6$. In this case, the potential in Einstein frame has a plateau at a large field limit, $\phi \gg \max\left(\frac{\xi_2}{\xi_3}, \sqrt{\frac{\lambda_4}{\lambda_6}}\right)$ as $V \sim \frac{V_J}{\Omega^4} \sim \frac{\lambda_6}{\xi_3^2} \left(1 - \frac{\xi_2}{\xi_3 \phi} + \frac{\lambda_4}{\lambda_6 \phi^2}\right)$, which is universal as long as $\lim_{\phi \rightarrow \infty} \frac{V_J}{\Omega^4} \rightarrow \text{const.}$ [63]. In this case inflationary dynamics would happen at a lower regime $\phi < \frac{\xi_2}{\xi_3}, \sqrt{\frac{\lambda_4}{\lambda_6}}$.

where V is the Einstein-frame potential $V = V_J/\Omega^4$ and χ is the canonical inflaton field in this frame. The relation between χ and the Jordan-frame inflaton ϕ depends on the formalism:

$$\frac{d\chi}{d\phi} = \begin{cases} \sqrt{\frac{1}{\Omega^2} + \frac{3}{2} \left(\frac{d \ln \Omega^2}{d\phi} \right)^2} & \text{(metric),} \\ \frac{1}{\Omega} & \text{(Palatini).} \end{cases} \quad (2.5)$$

The slow-roll parameters and the e -folding are calculated through

$$\epsilon = \frac{1}{2} \left(\frac{dV/d\chi}{V} \right)^2 = \frac{1}{2} \left(\frac{dV/d\phi}{V} \right)^2 \frac{1}{(d\chi/d\phi)^2}, \quad (2.6)$$

$$\eta = \frac{d^2V/d\chi^2}{V} = \left[\frac{d^2V/d\phi^2}{V} \frac{1}{(d\chi/d\phi)^2} - \frac{dV/d\phi}{V} \frac{d^2\chi/d\phi^2}{(d\chi/d\phi)^3} \right], \quad (2.7)$$

$$N = \int \frac{d\chi}{\sqrt{2\epsilon}} = \int \frac{d\phi}{d \ln V/d\phi} \left(\frac{d\chi}{d\phi} \right)^2, \quad (2.8)$$

and the resulting inflationary predictions are expressed by

$$A_s = \frac{1}{24\pi^2} \frac{V}{\epsilon}, \quad n_s = 1 - 6\epsilon + 2\eta, \quad r = 16\epsilon. \quad (2.9)$$

We use $A_s = 2.1 \times 10^{-9}$ (Planck TT,TE,EE+lowE+lensing+BK14+BAO [9]) throughout our analysis.

2.2 Standard predictions without higher dimensional operators

Before including higher dimensional operators in sections 3 and 4, let us review the inflationary predictions in the simplest setup. We truncate the Weyl-rescaling factor and the Jordan-frame potential as

$$\Omega^2 = 1 + \xi_2 \phi^2, \quad V_J = \lambda_4 \phi^4, \quad (2.10)$$

for both metric and Palatini formalisms. The Einstein-frame potential becomes

$$V = \frac{\lambda_4 \phi^4}{(1 + \xi_2 \phi^2)^2}. \quad (2.11)$$

Metric formalism. In the metric formalism, the relation (2.5) between χ and ϕ becomes

$$\frac{d\chi}{d\phi} = \frac{\sqrt{1 + \xi_2 (1 + 6\xi_2) \phi^2}}{1 + \xi_2 \phi^2}, \quad (2.12)$$

and the integral of the e -folding (2.8) can be exactly performed:

$$N = \frac{1}{8} [(1 + 6\xi_2) \phi^2 - 6 \ln (1 + \xi_2 \phi^2)], \quad (2.13)$$

where we have defined N as the number of e -folding from $\phi = 0$. Note that generically the difference between this definition and the usual one measured from $\max(|\epsilon|, |\eta|) = 1$ is suppressed by $1/N$ in the expression of $\phi(N)$.

Eq. (2.12) can be solved as⁹

$$\chi(\phi) = \sqrt{\frac{1+6\xi_2}{\xi_2}} \operatorname{arcsinh} \left[\sqrt{\xi_2(1+6\xi_2)}\phi \right] - \sqrt{6} \operatorname{arctanh} \left[\frac{\sqrt{6\xi_2}\phi}{\sqrt{1+\xi_2(1+6\xi_2)\phi^2}} \right]. \quad (2.14)$$

Although this is an exact formula, it is hardly inverted in general. However, in the limit $\xi_2 \gg 1$, the new kinetic term $\sim (\partial \ln \Omega^2)^2$ originating from the Ricci scalar dominates over the original kinetic term $\sim (\partial\phi)^2$ of the inflaton field, and thus the canonical inflaton field is well approximated as

$$\chi \simeq \sqrt{\frac{3}{2}} \ln \Omega^2 = \sqrt{\frac{3}{2}} \ln(1 + \xi_2 \phi^2). \quad (2.15)$$

Substituting this back to the potential, we get

$$V \simeq \frac{\lambda_4}{\xi_2^2} \left(1 - e^{-\sqrt{\frac{2}{3}}\chi} \right)^2. \quad (2.16)$$

The slow-roll parameters with this potential are calculated as

$$\epsilon \simeq \frac{4}{3} e^{-2\sqrt{\frac{2}{3}}\chi} \simeq \frac{3}{4N^2}, \quad \eta \simeq -\frac{4}{3} e^{-\sqrt{\frac{2}{3}}\chi} \simeq -\frac{1}{N}, \quad (2.17)$$

with the e -folding given by

$$N \simeq \frac{3}{4} e^{\sqrt{\frac{2}{3}}\chi}. \quad (2.18)$$

The inflationary predictions become

$$A_s \simeq \frac{N^2}{32\pi^2} \frac{\lambda_4}{\xi_2^2}, \quad n_s \simeq 1 - \frac{2}{N}, \quad r \simeq \frac{12}{N^2}. \quad (\text{Metric}) \quad (2.19)$$

In the expression of n_s , the deviation from unity is dominated by the contribution from η in eq. (2.9).

Calculations above are performed in terms of the canonical inflaton χ in the Einstein frame. From eq. (2.13), we can read off the behavior of ϕ for $\xi_2 \gg 1$ as

$$\phi \simeq \sqrt{\frac{4N}{3\xi_2}}, \quad (2.20)$$

which is consistent with eqs. (2.15) and (2.18). We see that the value of ϕ for a fixed e -folding scales as $\propto 1/\sqrt{\xi_2}$.¹⁰ This scaling behavior turns out to be important in interpreting our results later.

⁹The following formulae are useful: for $-1 < x < 1$,

$$\operatorname{arcsinh} x = \ln \left(x + \sqrt{1+x^2} \right), \quad \operatorname{arctanh} x = \frac{1}{2} \ln \left(\frac{1+x}{1-x} \right).$$

¹⁰In general, for monomial functions $\Omega^2 = 1 + \xi_m \phi^m$ and $V_I \propto \phi^{2m}$, the scaling behavior is $\phi \simeq \left(\frac{4N}{3\xi_m} \right)^{1/m}$ with $m \geq 2$ [63].

Palatini formalism. In Palatini formalism, the relation (2.5) becomes

$$\frac{d\chi}{d\phi} = \frac{1}{\sqrt{1 + \xi_2 \phi^2}}, \quad (2.21)$$

and the e -folding (2.8) is obtained as

$$N = \frac{\phi^2}{8} \quad \leftrightarrow \quad \phi = \sqrt{8N}, \quad (2.22)$$

where we have again defined N as the number of e -folding from $\phi = 0$. We see that the relation is independent of ξ_2 in contrast to the metric formalism. We also see that the value of $\phi_{\text{Palatini}} \sim \sqrt{N}$ at a given e -folding N is significantly larger than that in metric one, $\phi_{\text{metric}} \sim \sqrt{N/\xi_2}$ for $\xi_2 \gg 1$ in eq. (2.20).

Again one can exactly solve eq. (2.21):

$$\chi = \frac{1}{\sqrt{\xi_2}} \operatorname{arcsinh} \left[\sqrt{\xi_2} \phi \right] = \frac{1}{\sqrt{\xi_2}} \ln \left[\sqrt{\xi_2} \phi + \sqrt{1 + \xi_2 \phi^2} \right] \quad \leftrightarrow \quad \phi = \frac{1}{\sqrt{\xi_2}} \sinh \left[\sqrt{\xi_2} \chi \right], \quad (2.23)$$

and the Einstein-frame potential becomes

$$V = \frac{\lambda_4}{\xi_2^2} \tanh^4 \left[\sqrt{\xi_2} \chi \right]. \quad (2.24)$$

In the limit $\sqrt{\xi_2} \chi \gg 1$, we see

$$\phi \simeq \frac{1}{2\sqrt{\xi_2}} e^{\sqrt{\xi_2} \chi}, \quad N \simeq \frac{1}{32\xi_2} e^{2\sqrt{\xi_2} \chi}, \quad (2.25)$$

and the slow-roll parameters become

$$\epsilon \simeq 128\xi_2 e^{-4\sqrt{\xi_2} \chi} \simeq \frac{1}{8N^2\xi_2}, \quad \eta \simeq -32\xi_2 e^{-2\sqrt{\xi_2} \chi} \simeq -\frac{1}{N}. \quad (2.26)$$

From the expression of η we see that the inflation ends at $\chi \simeq \frac{\ln(32\xi_2)}{2\sqrt{\xi_2}} \ll 1$ for $\xi_2 \gg 1$, which corresponds to $\phi \simeq 2\sqrt{2}$. The curvature perturbation and other inflationary observables become

$$A_s \simeq \frac{N^2 \lambda_4}{3\pi^2 \xi_2}, \quad n_s \simeq 1 - \frac{2}{N}, \quad r \simeq \frac{2}{N^2 \xi_2}. \quad (\text{Palatini}) \quad (2.27)$$

In the expression of n_s , the deviation from unity is dominated by the contribution from η in eq. (2.9), similarly to the metric formalism. Note that the scaling $A_s \propto 1/\xi_2$ in Palatini formalism is different from $A_s \propto 1/\xi_2^2$ in metric one. Also, the tensor-to-scalar ratio r is multiplicatively suppressed by a factor of $1/\xi_2 \ll 1$ in contrast to the metric formalism.

3 Sensitivity to corrections in the Weyl-rescaling factor

The original truncation (2.10) takes into account up to the next-to-leading and leading terms in V_J and Ω^2 , respectively. We naturally expect further terms arising from radiative corrections and from new physics effects. Without knowing all sources of corrections, we phenomenologically parametrize the corrections by introducing higher dimensional operators as in eq. (2.2).

To be specific, we first consider the correction to the Weyl rescaling factor Ω^2 in both metric and Palatini formalisms in detail and see their effects to the inflationary dynamics and observables. Correction to the Jordan-frame potential will be discussed in section 4. Throughout both the analysis, we assume that $|\xi_{p>2}| \ll \xi_2$ and $|\lambda_{q>4}| \ll \lambda_4$ so that the success of the original Higgs-like inflation with nonminimal coupling $\xi_2 \gg 1$ is maintained.

The first case we consider is a correction to the Weyl rescaling factor:

$$\Omega^2 = 1 + \xi_2 \phi^2 + \xi_4 \phi^4, \quad V_J = \lambda_4 \phi^4. \quad (3.1)$$

Here we take into account the correction to Ω^2 only, and leave the correction to V_J for the later section. We fix their signs of ξ_2 and λ_4 to be positive, while we allow both positive and negative values for ξ_4 . Now the Einstein-frame potential becomes

$$V = \frac{\lambda_4 \phi^4}{(1 + \xi_2 \phi^2 + \xi_4 \phi^4)^2}. \quad (3.2)$$

In this setup we have three parameters

$$(\lambda_4, \xi_2, \xi_4),$$

but we can eliminate one of them by fixing the observed value of A_s , which we take to be $A_s = 2.1 \times 10^{-9}$ (Planck TT,TE,EE+lowE+lensing+BK14+BAO [9]) as mentioned above.

3.1 Predictions

Metric formalism. In metric formalism, the relation (2.5) between χ and ϕ becomes

$$\frac{d\chi}{d\phi} = \frac{\sqrt{1 + \xi_2 \phi^2 + \xi_4 \phi^4 + 6(\xi_2 \phi + 2\xi_4 \phi^3)^2}}{1 + \xi_2 \phi^2 + \xi_4 \phi^4}. \quad (3.3)$$

The slow-roll parameters and e -folding are calculated through eqs. (2.6)–(2.8):

$$\epsilon = \frac{8(1 - \xi_4 \phi^4)^2}{\phi^2 [1 + (\xi_2 + 6\xi_2^2) \phi^2 + (\xi_4 + 24\xi_2 \xi_4) \phi^4 + 24\xi_4^2 \phi^6]}, \quad (3.4)$$

$$\eta = \frac{4 [3 + (\xi_2 + 12\xi_2^2) \phi^2 + (-2\xi_2^2 - 12\xi_2^3 + 24\xi_2 \xi_4 - 11\xi_4) \phi^4 + \dots + 96\xi_4^4 \phi^{14}]}{\phi^2 [1 + (\xi_2 + 6\xi_2^2) \phi^2 + (\xi_4 + 24\xi_2 \xi_4) \phi^4 + 24\xi_4^2 \phi^6]^2}, \quad (3.5)$$

$$N = \frac{1 + 6\xi_2}{16\sqrt{\xi_4}} \ln \left[\frac{1 + \sqrt{\xi_4} \phi^2}{1 - \sqrt{\xi_4} \phi^2} \right] - \frac{3}{4} \ln [(1 - \xi_4 \phi^4) (1 + \xi_2 \phi^2 + \xi_4 \phi^4)]. \quad (3.6)$$

Here we do not show a complete expression for η just to avoid complications; see appendix A for it. Note that the e -folding diverges for $\xi_4 > 0$ at $\phi = \xi_4^{-1/4}$, which corresponds to the point where the potential derivative vanishes. The scalar power spectrum amplitude reads

$$A_s = \frac{\lambda_4 \phi^6}{192\pi^2} \frac{1 + \xi_2 (1 + 6\xi_2) \phi^2 + (1 + 24\xi_2) \xi_4 \phi^4 + 24\xi_4^2 \phi^6}{(1 - \xi_4 \phi^4)^2 (1 + \xi_2 \phi^2 + \xi_4 \phi^4)^2}. \quad (3.7)$$

Palatini formalism. In Palatini formalism, the relation (2.5) becomes

$$\frac{d\chi}{d\phi} = \frac{1}{\sqrt{1 + \xi_2\phi^2 + \xi_4\phi^4}}, \quad (3.8)$$

which can be explicitly solved as shown in appendix A. Also, from eqs. (2.6)–(2.8), the slow-roll parameters and e -folding become

$$\epsilon = \frac{8(1 - \xi_4\phi^4)^2}{\phi^2 [1 + \xi_2\phi^2 + \xi_4\phi^4]}, \quad (3.9)$$

$$\eta = \frac{4(3 - 2\xi_2\phi^2 - 14\xi_4\phi^4 - 2\xi_2\xi_4\phi^6 + 3\xi_4^2\phi^8)}{\phi^2 [1 + \xi_2\phi^2 + \xi_4\phi^4]}, \quad (3.10)$$

$$N = \frac{1}{16\sqrt{\xi_4}} \ln \left[\frac{1 + \sqrt{\xi_4}\phi^2}{1 - \sqrt{\xi_4}\phi^2} \right] \quad \leftrightarrow \quad \phi = \xi_4^{-1/4} \sqrt{\tanh \left[8\sqrt{\xi_4}N \right]}, \quad (3.11)$$

where we inverted the relation in the last equality. Note that the e -folding diverges at the same point $\phi = \xi_4^{-1/4}$ as the metric formalism for $\xi_4 > 0$ because the potential derivative vanishes there. The scalar power spectrum amplitude reads

$$A_s = \frac{\lambda_4\phi^6}{192\pi^2} \frac{1}{(1 - \xi_4\phi^4)^2 (1 + \xi_2\phi^2 + \xi_4\phi^4)}. \quad (3.12)$$

3.2 Results

In figure 1, we show predictions of the metric (left) and Palatini (right) formalisms in the n_s - r plane for $N = 60$ (top) and 50 (bottom). The blue contours show constant values of ξ_2 , while the red ones show constant values of ξ_4 . The value of the quartic coupling λ_4 is also presented as a density plot. The smiley marker is the prediction of the quartic chaotic inflation, while the star denotes the attractor point for $\xi_2 \gg 1$. For $\xi_2 < 10^{-3}$ and $\xi_2 > 1$, the corresponding blue lines are almost degenerate with the upper and lower boundaries with the gray regions, respectively. We see the following:

- For relatively small ξ_2 ($\lesssim 10^{-1}$), even a small injection of $|\xi_4| \gtrsim 10^{-5}$ drastically changes the inflationary predictions in both metric and Palatini formalisms.
- For relatively large ξ_2 ($\gtrsim 1$), the inflationary predictions are stable against the injection of ξ_4 for the metric formalism (left): we see that all the red lines converge to the attractor point. On the other hand, the predictions are no more stable against the injection of $|\xi_4| \gtrsim 10^{-5}$ for the Palatini formalism (right).

In figure 2, we plot the behavior of λ_4 as a function of $|\xi_4|$ for $\xi_4 < 0$ (left panel) and $\xi_4 > 0$ (right panel) with $N = 60$ for fixed values of ξ_2 . In figure 3, we plot n_s (solid, left axis) and r (dashed, right axis) similarly. Figures 4 and 5 are the corresponding ones with $N = 50$. One immediately sees that the deviation from the attractor occurs around $|\xi_4| \sim 10^{-4}\xi_2^2$ and around $|\xi_4| \sim 10^{-5}$ for the metric and Palatini cases, respectively.

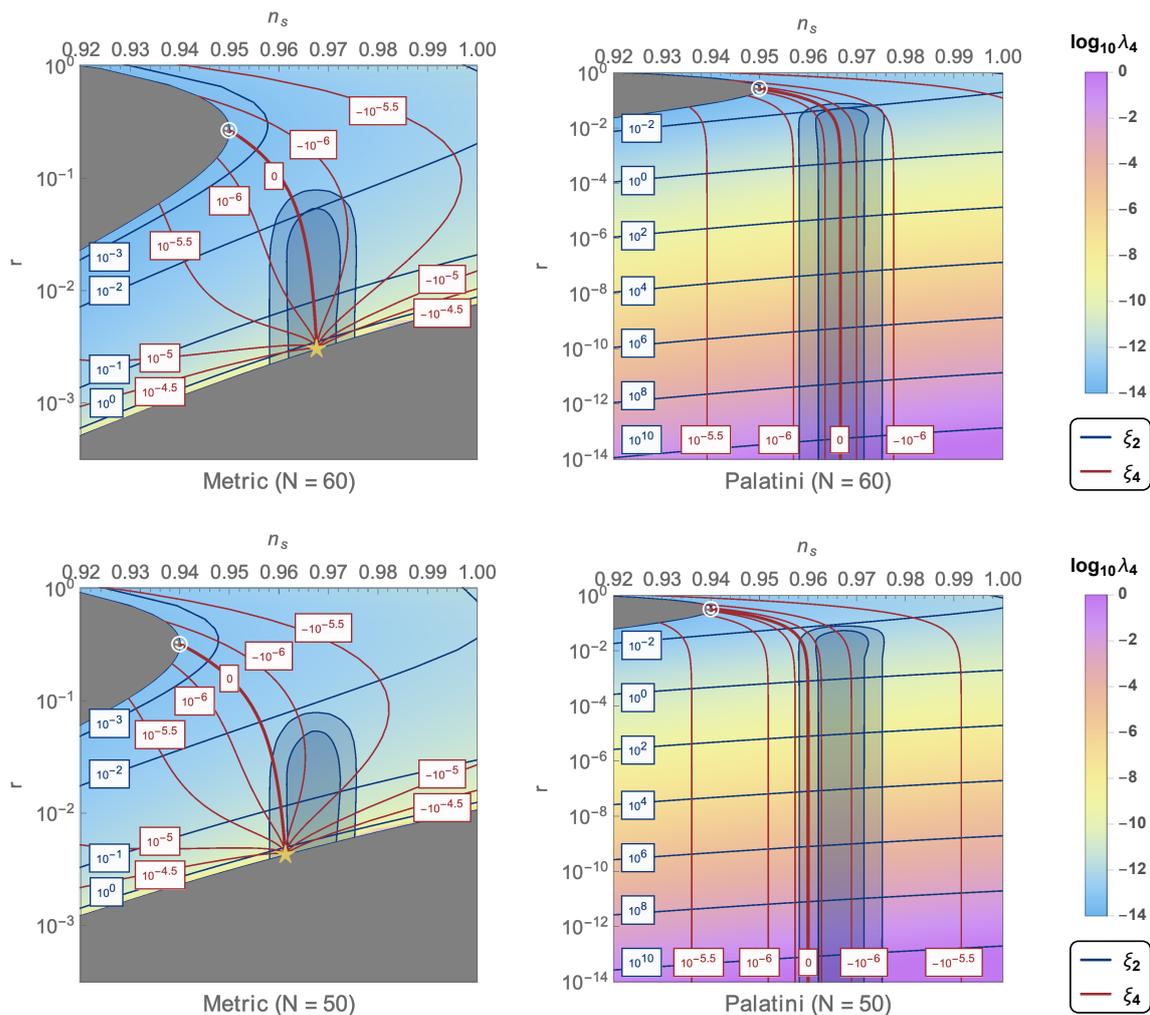

Figure 1. Effects of the higher dimensional operator $\xi_4 \phi^4 R_J$ in the metric (left) and Palatini (right) formalisms with $N = 60$ (top) and 50 (bottom). We plot contours of fixed ξ_2 (blue, horizontal) and of fixed ξ_4 (red, vertical) in the n_s - r plane. The value of λ_4 is also shown as a density plot. Allowed regions of 1σ and 2σ from the Planck experiment [9] (TT,TE,EE+lowE+lensing+BK14+BAO) are also shown in the center.

3.3 Interpretation

Let us interpret our results, especially the threshold value of ξ_4 which gives deviation from the observationally allowed region. In the following we use $N \gg 1$ and $\xi_2 \gg 1$ and keep the leading contribution for each order in ξ_4 expansion when necessary.

In the metric formalism, let us first expand eq. (3.6) by small ξ_4 around $\phi \simeq \phi_{\xi_4=0} \simeq \sqrt{4N/3\xi_2}$ (see eq. (2.20)):

$$N = \left[\frac{1 + 6\xi_2}{8} \phi^2 - \frac{3}{4} \ln(1 + \xi_2 \phi^2) \right] + \xi_4 \left[\frac{1 + 6\xi_2}{24} \phi^6 - \frac{3}{4} \frac{\xi_2 \phi^6}{1 + \xi_2 \phi^2} \right] + \dots \quad (3.13)$$

Substituting $\phi = \phi_{\xi_4=0}(1 + c\xi_4)$ and comparing leading terms in ξ_4 we find that the deviation of ϕ is given by

$$\phi \simeq \phi_{\xi_4=0} \left(1 - \frac{8N^2}{27\xi_2^2} \xi_4 \right). \quad (3.14)$$

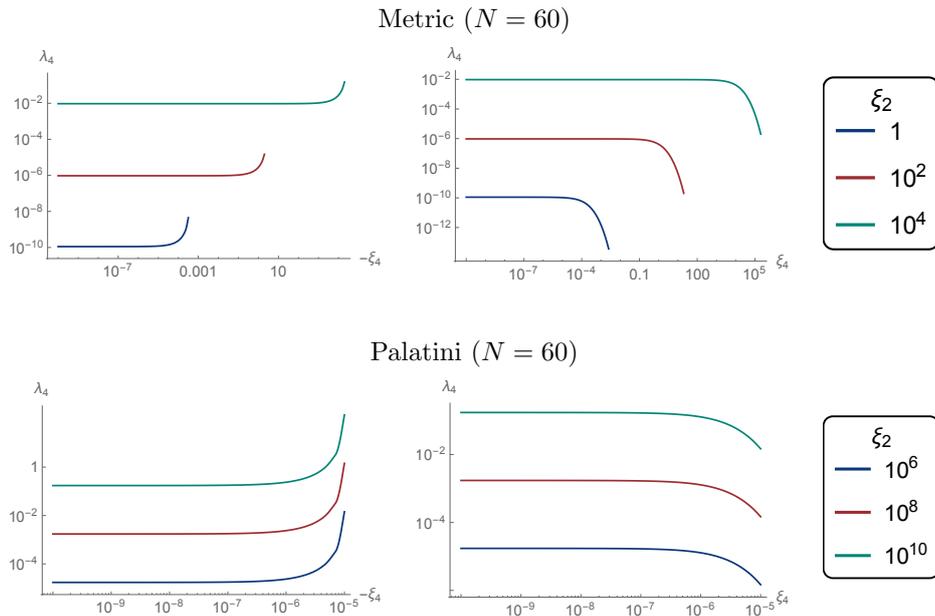

Figure 2. Behavior of λ_4 along constant ξ_2 slices in figure 1 for $N = 60$. We show λ_4 as a function of $|\xi_4|$ for $\xi_4 < 0$ (left) and $\xi_4 > 0$ (right). The lines are $\xi_2 = 1$ (blue), 10^2 (red), and 10^4 (green) for the metric case, while $\xi_2 = 10^6$ (blue), 10^8 (red), and 10^{10} (green) for the Palatini case.

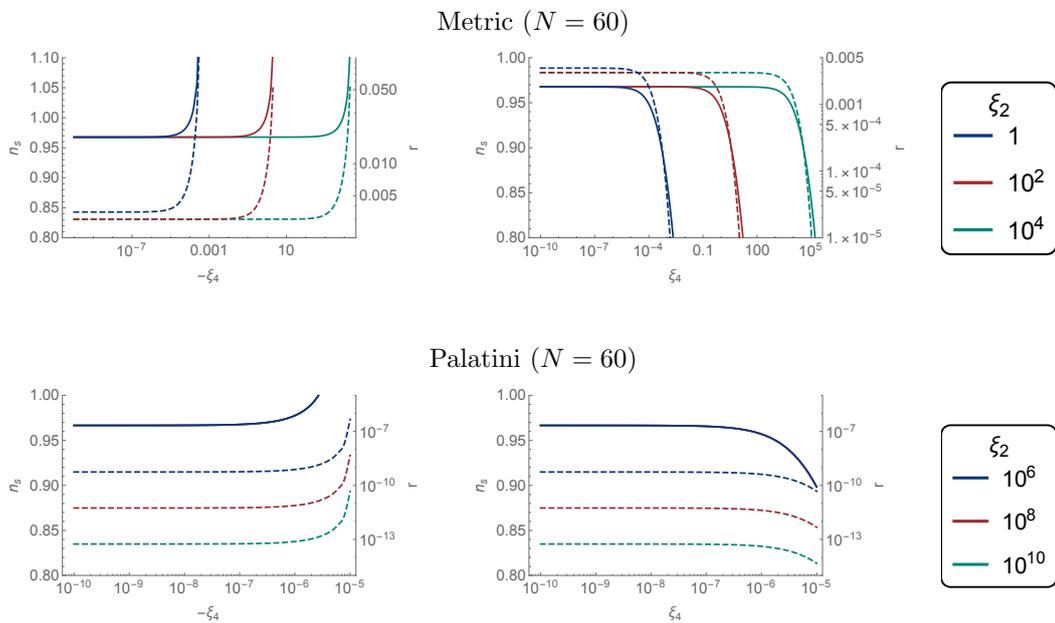

Figure 3. Behavior of n_s (solid, left axis) and r (dashed, right axis) along constant ξ_2 slices in figure 1 for $N = 60$. All the solid lines are degenerate for the Palatini case.

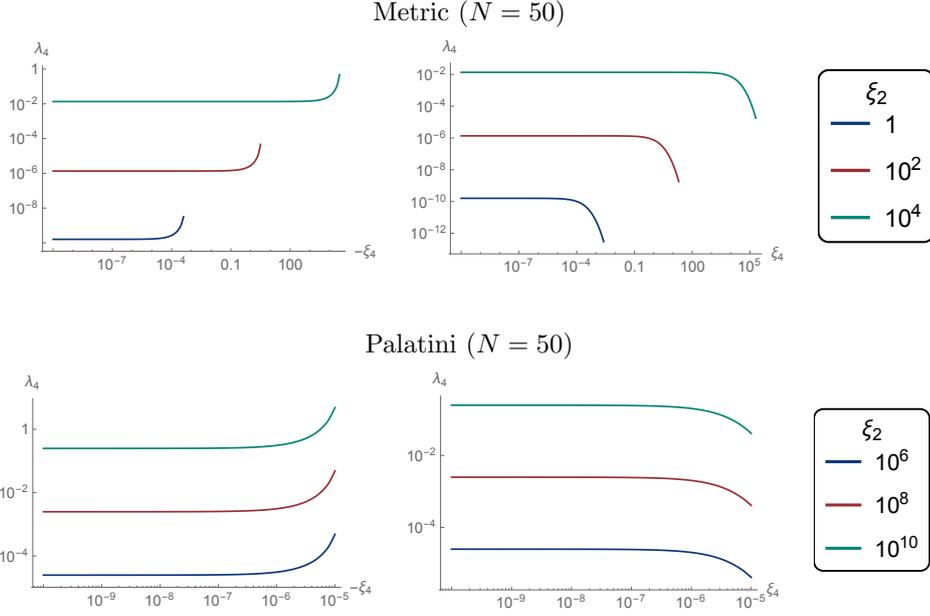

Figure 4. The same as in figure 2 except for $N = 50$.

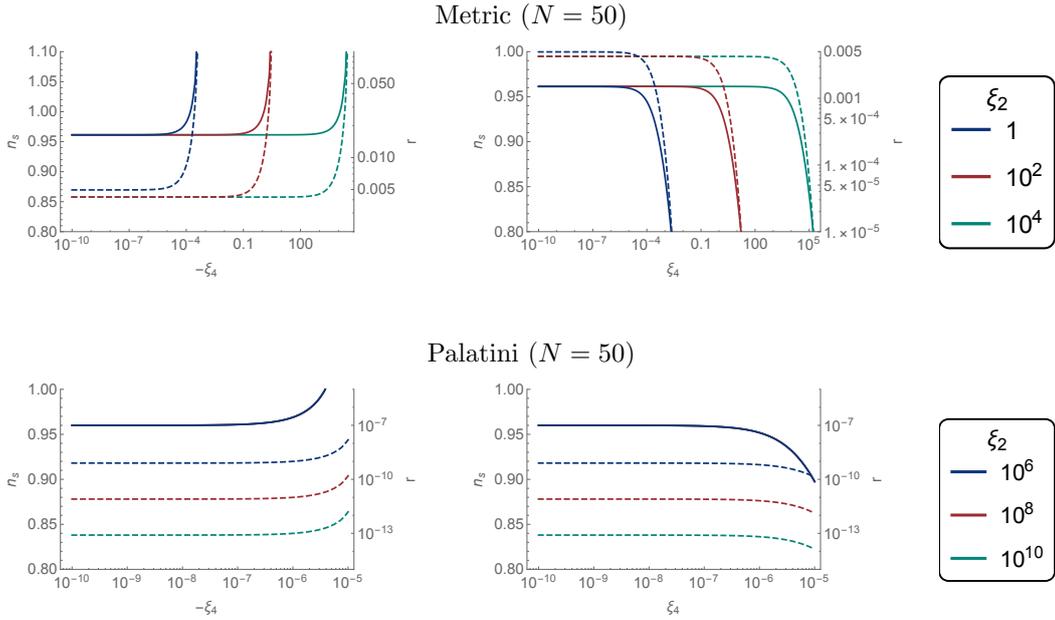

Figure 5. The same as in figure 3 except for $N = 50$.

We next expand ϵ (3.4) and η (3.5) by small ξ_4 around the same point of ϕ , and then substitute eq. (3.14):

$$\epsilon \simeq \frac{4}{3\xi_2^2\phi^4} (1 - 2\xi_4\phi^4) \simeq \frac{3}{4N^2} \left(1 - \frac{64N^2}{27\xi_2^2} \xi_4 \right), \quad (3.15)$$

$$\eta \simeq -\frac{4}{3\xi_2\phi^2} (1 + \xi_4\phi^4) \simeq -\frac{1}{N} \left(1 + \frac{64N^2}{27\xi_2^2} \xi_4 \right). \quad (3.16)$$

We see that the deviation becomes sizable for $|\xi_4| \gtrsim \xi_2^2/N^2$. Since ϵ and η corresponds to the r (vertical) and n_s (horizontal) axes in figure 1, respectively, the direction of deviation for positive and negative ξ_4 is also explained.

In the Palatini formalism, let us first expand eq. (3.11) by small ξ_4 around $\phi \simeq \phi_{\xi_4=0} \simeq \sqrt{8N}$ (see eq. (2.22)):

$$N = \frac{1}{8}\phi^2 + \frac{1}{24}\xi_4\phi^6 + \dots \quad (3.17)$$

Substituting $\phi = \phi_{\xi_4=0}(1 + c\xi_4)$ and comparing leading terms in ξ_4 , we find

$$\phi \simeq \phi_{\xi_4=0} \left(1 - \frac{32N^2}{3}\xi_4 \right). \quad (3.18)$$

We next expand ϵ (3.9) and η (3.10) by small ξ_4 around the same point of ϕ , and then substitute eq. (3.18):

$$\epsilon \simeq \frac{8}{\xi_2\phi^4} (1 - 2\xi_4\phi^4) \simeq \frac{1}{8N^2\xi_2} \left(1 - \frac{256N^2}{3}\xi_4 \right), \quad (3.19)$$

$$\eta \simeq -\frac{8}{\phi^2} (1 + \xi_4\phi^4) \simeq -\frac{1}{N} \left(1 + \frac{256N^2}{3}\xi_4 \right). \quad (3.20)$$

We see that the deviation becomes sizable for $|\xi_4| \gtrsim 10^{-2}/N^2$ and that the direction of the deviation is the same as in the metric formalism.

To summarize, the expressions for the slow-roll parameters, especially for η , imply that the inflationary predictions (especially on n_s) are significantly affected for

$$|\xi_4| \gtrsim \begin{cases} \frac{\xi_2^2}{N^2} & \text{(metric),} \\ \frac{10^{-2}}{N^2} & \text{(Palatini).} \end{cases} \quad (3.21)$$

This explains the behavior in figures 2–5. After taking the curvature normalization into account, these values read

$$|\xi_4| \gtrsim \begin{cases} \frac{\xi_2^2}{N^2} \sim \frac{\lambda_4}{32\pi^2 A_s} \sim 10^6 \lambda_4 & \text{(metric),} \\ \frac{10^{-2}}{N^2} & \text{(Palatini).} \end{cases} \quad (3.22)$$

Therefore, we see that the inflationary predictions in the metric formalism become stable for $\xi_2 \gg 1$ (unless $\lambda_4 \ll 10^{-6}$), while they are spoiled by $|\xi_4| \sim 10^{-5}$ independently of λ_4 or ξ_2 in the Palatini formalism.

In the case $\xi_4 > 0$, we note that in both the formalisms ϵ becomes zero at $\xi_4\phi^4 = 1$ and hence the e -folding diverges in the limit $\phi \rightarrow \xi_4^{-1/4}$. Then the necessary condition $\phi < \xi_4^{-1/4}$ at $\phi \sim \sqrt{4N/3\xi_2}$ (metric) and $\phi \sim \sqrt{8N}$ (Palatini) reads

$$\xi_4 \lesssim \begin{cases} \frac{9\xi_2^2}{16N^2} & \text{(metric),} \\ \frac{1}{64N^2} & \text{(Palatini).} \end{cases} \quad (3.23)$$

Note that we used the relation between ϕ and N for $\xi_4 = 0$ (and for $\xi_2 \gg 1$ in metric formalism), and therefore these conditions are only approximate. We see that these conditions give comparable threshold values to eq. (3.21).

As we increase $|\xi_4|$ from zero, the inflationary prediction starts to deviate at around the value in the right-hand side of eq. (3.21). We note that this occurs when the higher dimensional operator $|\xi_4\phi^4|$ is still much smaller than the lower dimensional one $\xi_2\phi^2$. Indeed, by substituting the approximate values $\phi \simeq \sqrt{4N/3\xi_2}$ (metric) and $\sqrt{8N}$ (Palatini), the condition

$$|\xi_4\phi^4| \lesssim \xi_2\phi^2 \quad (3.24)$$

becomes

$$|\xi_4| \lesssim \begin{cases} \frac{\xi_2^2}{N} & \text{(metric),} \\ 10^{-1} \frac{\xi_2}{N} & \text{(Palatini),} \end{cases} \quad (3.25)$$

which is well satisfied at the value in the right-hand side of eq. (3.21).

4 Sensitivity to corrections in the potential

Second, we consider a correction to the Jordan-frame potential:

$$\Omega^2 = 1 + \xi_2\phi^2, \quad V_J = \lambda_4\phi^4 + \lambda_6\phi^6. \quad (4.1)$$

Again we fix the signs of ξ_2 and λ_4 to be positive, while we allow both positive and negative signs for λ_6 . The Einstein-frame potential becomes

$$V = \frac{\lambda_4\phi^4 + \lambda_6\phi^6}{(1 + \xi_2\phi^2)^2}. \quad (4.2)$$

In this setup we have three parameters

$$(\lambda_4, \lambda_6, \xi_2),$$

but we can eliminate one since A_s is fixed by the observation.

4.1 Predictions

Before discussing predictions in each formalism, we note that the dependence of ϵ , η , and N on λ_4 and λ_6 shown below appears only through the ratio λ_6/λ_4 . In the following analysis, we fix the quartic coupling λ_4 by the overall normalization A_s and adopt λ_6/λ_4 as an independent variable instead of λ_6 .

Metric formalism. In the metric formalism, the relation (2.5) between χ and ϕ is the same as eqs. (2.12)–(2.14). The slow-roll parameters and e -folding are calculated through eqs. (2.6)–(2.8):

$$\epsilon = \frac{2(2\lambda_4 + 3\lambda_6\phi^2 + \xi_2\lambda_6\phi^4)^2}{\phi^2 [1 + (\xi_2 + 6\xi_2^2)\phi^2] (\lambda_4 + \lambda_6\phi^2)^2}, \quad (4.3)$$

$$\eta = \frac{2[6\lambda_4 + (2\xi_2\lambda_4 + 24\xi_2^2\lambda_4 + 15\lambda_6)\phi^2 + \dots + (2\xi_2^3\lambda_6 + 12\xi_2^4\lambda_6)\phi^8]}{\phi^2 [1 + (\xi_2 + 6\xi_2^2)\phi^2]^2 (\lambda_4 + \lambda_6\phi^2)}, \quad (4.4)$$

$$N = \int d\phi \frac{\phi [1 + (\xi_2 + 6\xi_2^2)\phi^2] (\lambda_4 + \lambda_6\phi^2)}{2(1 + \xi_2\phi^2)(2\lambda_4 + 3\lambda_6\phi^2 + \xi_2\lambda_6\phi^4)}. \quad (4.5)$$

Here we do not show a complete expression for η to avoid complications; see appendix A for it. Note that for $\lambda_6 < 0$ the e -folding diverges at the point where the potential derivative vanishes, namely, at $\phi = \sqrt{-3 + \sqrt{9 - 8\xi_2\lambda_4/\lambda_6/2\xi_2}}$. The scalar power spectrum amplitude reads

$$A_s = \frac{\lambda_4\phi^6}{192\pi^2} \frac{[1 + \xi_2\phi^2(1 + 6\xi_2)] \left(1 + \frac{\lambda_6}{\lambda_4}\phi^2\right)^3}{(1 + \xi_2\phi^2) \left[1 + \frac{3\lambda_6}{2\lambda_4}\phi^2 \left(1 + \frac{\xi_2}{3}\phi^2\right)\right]^2}. \quad (4.6)$$

Palatini formalism. In the Palatini formalism, the relation (2.5) between χ and ϕ is the same as eqs. (2.21)–(2.23). The slow-roll parameters and e -folding are calculated through eqs. (2.6)–(2.8):

$$\epsilon = \frac{2(2\lambda_4 + 3\lambda_6\phi^2 + \xi_2\lambda_6\phi^4)^2}{\phi^2(1 + \xi_2\phi^2)(\lambda_4 + \lambda_6\phi^2)^2}, \quad (4.7)$$

$$\eta = \frac{2[6\lambda_4 + (-4\xi_2\lambda_4 + 15\lambda_6)\phi^2 + 7\xi_2\lambda_6\phi^4 + 2\xi_2^2\lambda_6\phi^6]}{\phi^2(1 + \xi_2\phi^2)(\lambda_4 + \lambda_6\phi^2)}, \quad (4.8)$$

$$N = \int d\phi \frac{\phi(\lambda_4 + \lambda_6\phi^2)}{2(2\lambda_4 + 3\lambda_6\phi^2 + \xi_2\lambda_6\phi^4)}. \quad (4.9)$$

For $\lambda_6 < 0$, the e -folding diverges at the same point as the metric formalism, where the potential derivative vanishes. The scalar power spectrum amplitude reads

$$A_s = \frac{\lambda_4\phi^6}{192\pi^2} \frac{\left(1 + \frac{\lambda_6}{\lambda_4}\phi^2\right)^3}{(1 + \xi_2\phi^2) \left[1 + \frac{3\lambda_6}{2\lambda_4}\phi^2 \left(1 + \frac{\xi_2}{3}\phi^2\right)\right]^2}. \quad (4.10)$$

4.2 Results

First in figure 6, we show predictions of the metric (left) and Palatini (right) formalisms at $N = 60$ (top) and 50 (bottom) in the n_s - r plane. The blue contours show constant values of ξ_2 , while the red ones show constant values of λ_6/λ_4 . The value of λ_4 is also shown as a density plot. The smiley marker is the prediction of the quartic chaotic inflation, while the star denotes the attractor point $\xi_2 \gg 1$. For $\xi_2 < 10^{-3}$ and $\xi_2 > 1$, the corresponding blue lines are almost degenerate with the upper and lower boundaries with the gray regions, respectively. We see the following:

- For relatively small ξ_2 ($\lesssim 10^{-1}$), even a small injection of $|\lambda_6/\lambda_4|$ drastically changes the inflationary predictions in both formalisms.
- For relatively large ξ_2 ($\gtrsim 1$), the inflationary predictions are stable against the injection of λ_6/λ_4 for the metric formalism (left), just as section 3. On the other hand, the predictions are no more stable against the injection of $|\lambda_6/\lambda_4| \gtrsim 10^{-5}\xi_2^{-1}$ for the Palatini formalism (right).

In figure 7, we plot the behavior of λ_4 for $N = 60$ as a function of $|\lambda_6/\lambda_4|$ for $\lambda_6/\lambda_4 < 0$ (left panel) and $\lambda_6/\lambda_4 > 0$ (right panel) while fixing the overall normalization A_s as mentioned above. Similarly, in figure 8 we plot n_s (left axis) and r (right axis). Figures 9 and 10 are the corresponding ones at $N = 50$. We note the following:

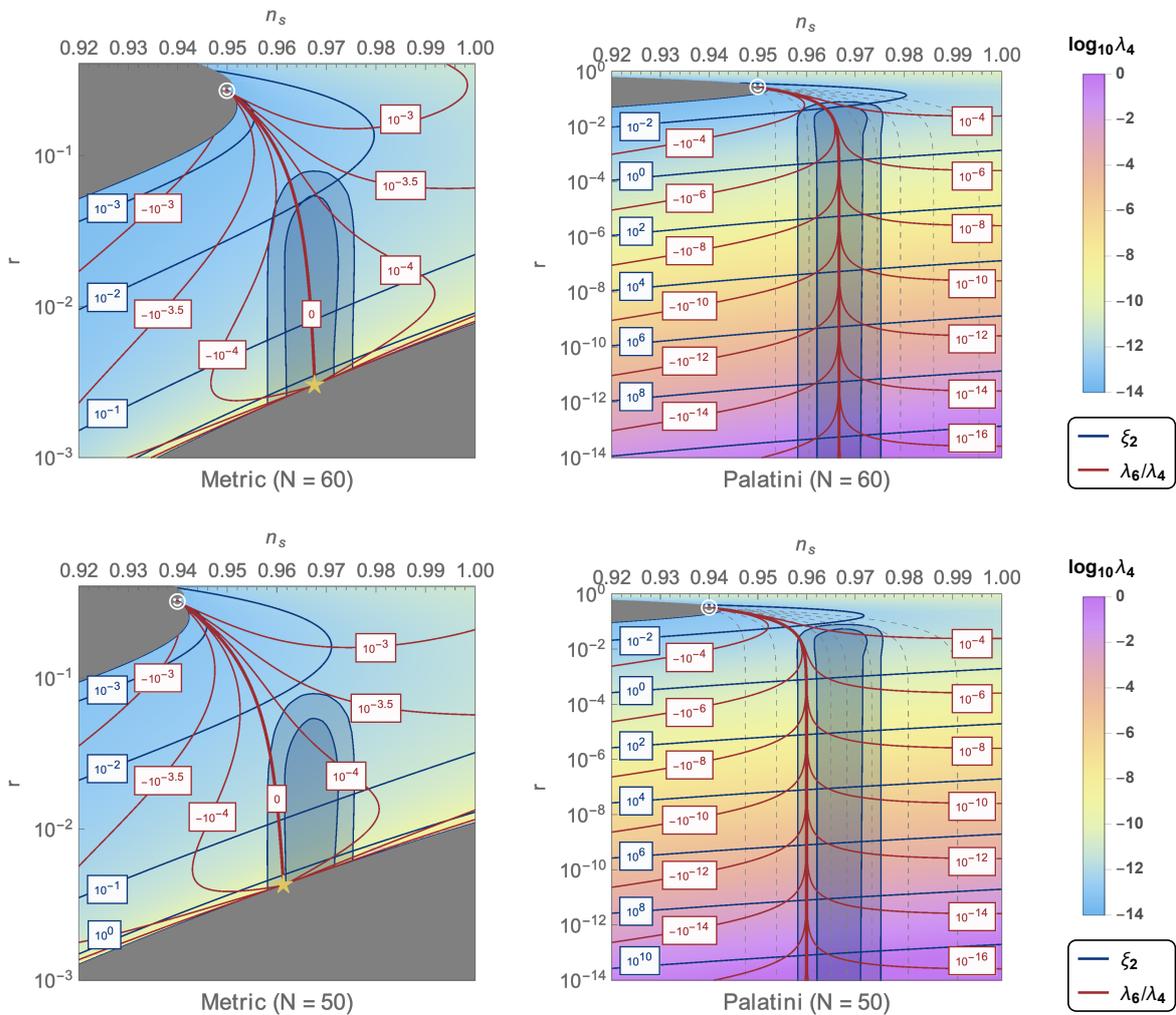

Figure 6. Effects of the higher dimensional operator $\lambda_6 \phi^6$ in the metric (left) and Palatini (right) formalisms with $N = 60$ (top) and 50 (bottom). We plot contours of fixed ξ_2 (blue, horizontal) and of fixed λ_6/λ_4 (red, vertical) in the n_s - r plane. The value of λ_4 is also shown as a density plot. Allowed regions of 1σ and 2σ from the Planck experiment [9] (TT,TE,EE+lowE+lensing+BK14+BAO) are also shown in the center. Dashed lines in the right panels correspond to $\lambda_6 = -10^{-16.25}, -16.5$ and $10^{-16.5}, -16.25, -16, -15.75, -15.5$ from left to right.

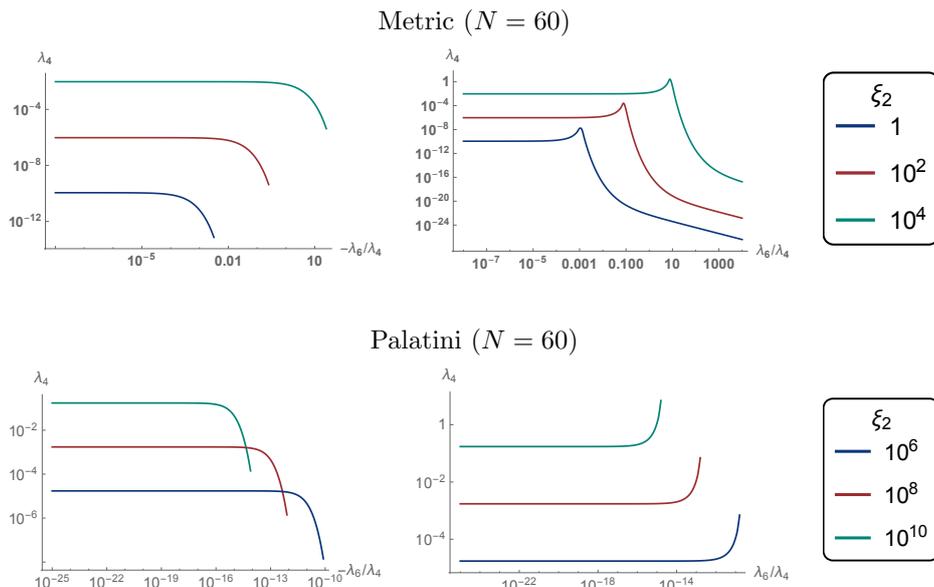

Figure 7. Behavior of λ_4 along constant ξ_2 slices in figure 6 for $N = 60$. We plot λ_4 as a function of $|\lambda_6/\lambda_4|$ for $\lambda_6/\lambda_4 < 0$ (left) and $\lambda_6/\lambda_4 > 0$ (right). The lines are $\xi_2 = 1$ (blue), 10^2 (red), and 10^4 (green) for the metric case, while $\xi_2 = 10^6$ (blue), 10^8 (red), and 10^{10} (green) for the Palatini case.

- In the metric formalism (upper panels of figures 7–10), deviation from the attractor occurs at the threshold $|\lambda_6/\lambda_4| \sim 10^{-3}\xi_2$. For $\lambda_6 < 0$ the behavior of n_s and r is relatively simple (upper left panels of figures 8 and 10): as $|\lambda_6/\lambda_4|$ increases, both n_s and r start to decrease at this threshold value. From the relation $n_s \simeq 1 - 6\epsilon + 2\eta$ and $r \simeq 16\epsilon$, we see that both ϵ and η start to decrease at this threshold value while keeping the relation $|\epsilon| \ll |\eta|$. On the other hand, for $\lambda_6 > 0$ the behavior of n_s and r is more complicated (upper right panels of figures 8 and 10): as $|\lambda_6/\lambda_4|$ increases, r reaches to $\mathcal{O}(1)$ values while n_s first increases and then decreases. From the relation $n_s \simeq 1 - 6\epsilon + 2\eta$ and $r \simeq 16\epsilon$, we see that as $|\lambda_6/\lambda_4|$ increases ϵ reaches to $\mathcal{O}(0.1)$ values and exceeds η , causing the decrease in n_s observed in the upper right panels of figures 8 and 10.
- In the Palatini formalism (lower panels of figures 7–10), there is no attractor for $\xi_2 \gg 1$ and the deviation from the observationally allowed region occurs around the threshold $|\lambda_6/\lambda_4| \sim 10^{-5}\xi_2^{-1}$.

4.3 Interpretation

Let us interpret our results and estimate the threshold value of λ_6 which causes significant deviation from the observationally allowed region. In the following we use $N \gg 1$ and $\xi_2 \gg 1$ and keep the leading contribution for each order in ξ_4 expansion when necessary.

In the metric formalism, let us first expand eq. (4.5) by small λ_6/λ_4 around $\phi \simeq \phi_{\lambda_6=0} \simeq \sqrt{4N/3\xi_2}$ (see eq. (2.20)):

$$N = \int d\phi \frac{\phi \cdot 6\xi_2^2 \phi^2 \cdot (\lambda_4 + \lambda_6 \phi^2)}{2 \cdot \xi_2 \phi^2 \cdot (2\lambda_4 + \xi_2 \lambda_6 \phi^4)} + \dots = \frac{3}{4} \xi_2 \phi^2 - \frac{1}{8} \frac{\lambda_6}{\lambda_4} \xi_2^2 \phi^6 + \dots \quad (4.11)$$

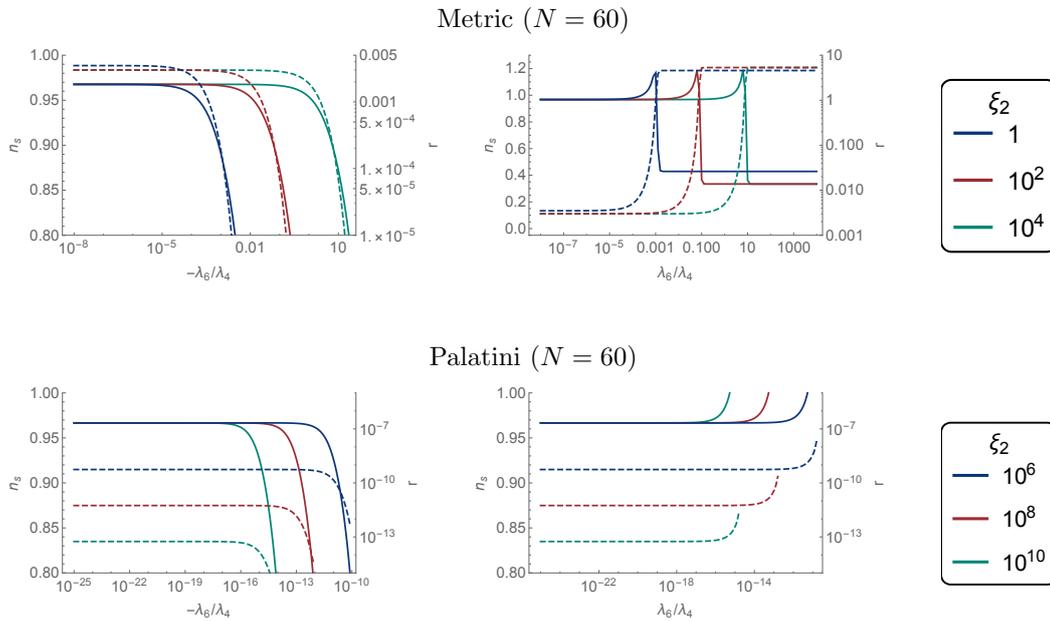

Figure 8. Behavior of n_s (solid, left axis) and r (dashed, right axis) along constant ξ_2 slices in figure 6 for $N = 60$.

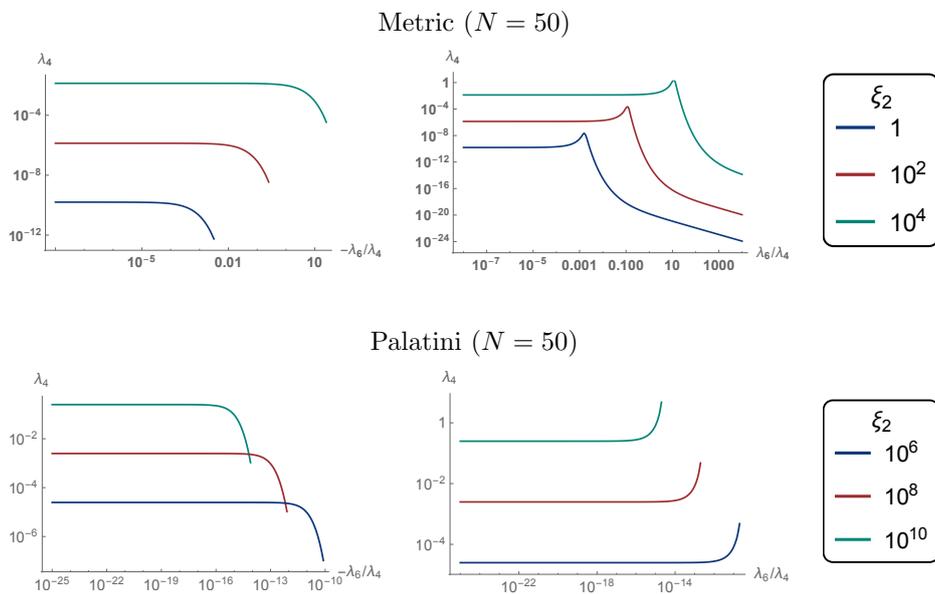

Figure 9. The same as in figure 7 except for $N = 50$.

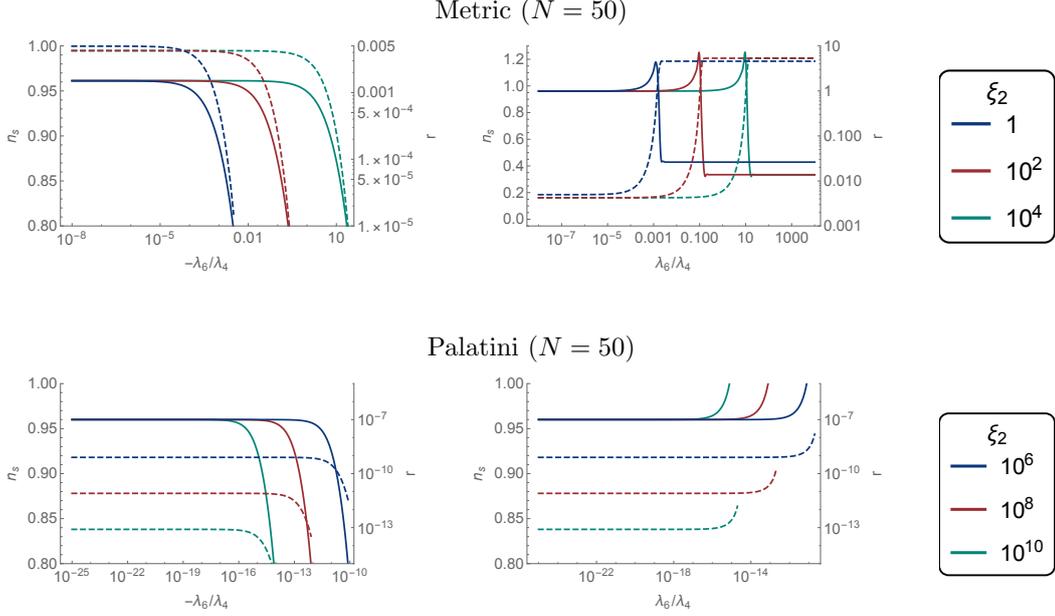

Figure 10. The same as in figure 8 except for $N = 50$.

Substituting $\phi = \phi_{\lambda_6=0}(1 + c(\lambda_6/\lambda_4))$ and comparing leading terms in λ_6/λ_4 , we find that the deviation of ϕ is given by

$$\phi \simeq \phi_{\lambda_6=0} \left(1 + \frac{4N^2 \lambda_6}{27\xi_2 \lambda_4} \right). \quad (4.12)$$

We next expand ϵ (4.3) and η (4.4) by small λ_6/λ_4 around the same point of ϕ , and then substitute eq. (4.12):

$$\epsilon \simeq \frac{4}{3\xi_2^2 \phi^4} \left(1 + \frac{\lambda_6}{\lambda_4} \xi_2 \phi^4 \right) \simeq \frac{3}{4N^2} \left(1 + \frac{32N^2 \lambda_6}{27\xi_2 \lambda_4} \right), \quad (4.13)$$

$$\eta \simeq -\frac{4}{3\xi_2 \phi^2} \left(1 - \frac{1}{2} \frac{\lambda_6}{\lambda_4} \xi_2 \phi^4 \right) \simeq -\frac{1}{N} \left(1 - \frac{32N^2 \lambda_6}{27\xi_2 \lambda_4} \right). \quad (4.14)$$

We see that the deviation of η (and hence of n_s) becomes sizable for $|\lambda_6/\lambda_4| \gtrsim \xi_2/N^2$. From the relation $n_s \simeq 1 - 6\epsilon + 2\eta$ and $r \simeq 16\epsilon$, the direction of deviation in figure 6 for positive and negative λ_6 with a fixed ξ_2 can also be explained.

In the Palatini formalism, let us first expand eq. (4.9) by small λ_6/λ_4 around $\phi \simeq \phi_{\lambda_6=0} \simeq \sqrt{8N}$ (see eq. (2.22)):

$$N = \int d\phi \frac{\phi \cdot (\lambda_4 + \lambda_6 \phi^2)}{2 \cdot (2\lambda_4 + \xi_2 \lambda_6 \phi^4)} + \dots = \frac{1}{8} \phi^2 - \frac{1}{48} \frac{\lambda_6}{\lambda_4} \xi_2 \phi^6 + \dots \quad (4.15)$$

Substituting $\phi = \phi_{\lambda_6=0}(1 + c(\lambda_6/\lambda_4))$ and comparing leading terms in λ_6/λ_4 , we find

$$\phi \simeq \phi_{\lambda_6=0} \left(1 + \frac{16N^2 \xi_2 \lambda_6}{3 \lambda_4} \right). \quad (4.16)$$

We next expand ϵ (4.7) and η (4.8) by small λ_6/λ_4 around the same point of ϕ , and then substitute eq. (4.16):

$$\epsilon \simeq \frac{8}{\xi_2 \phi^4} \left(1 + \frac{\lambda_6}{\lambda_4} \xi_2 \phi^4 \right) \simeq \frac{1}{8N^2 \xi_2} \left(1 + \frac{128N^2 \xi_2 \lambda_6}{3 \lambda_4} \right), \quad (4.17)$$

$$\eta \simeq -\frac{8}{\phi^2} \left(1 - \frac{1}{2} \frac{\lambda_6}{\lambda_4} \xi_2 \phi^4 \right) \simeq -\frac{1}{N} \left(1 - \frac{128N^2 \xi_2 \lambda_6}{3 \lambda_4} \right). \quad (4.18)$$

We see that the deviation of η (and hence of n_s) becomes sizable for $|\lambda_6/\lambda_4| \gtrsim 10^{-1}/N^2 \xi_2$ and that the direction of the deviation is the same as in the metric formalism.

To summarize, the deviation of η (and hence of n_s) becomes sizable for

$$|\lambda_6| \gtrsim \begin{cases} \frac{\lambda_4 \xi_2}{N^2} & \text{(metric),} \\ 10^{-1} \frac{\lambda_4}{N^2 \xi_2} & \text{(Palatini),} \end{cases} \quad (4.19)$$

while ϵ (and hence r) is rather insensitive compared to η . If we substitute λ_4 with A_s , we get

$$|\lambda_6| \gtrsim \begin{cases} 10^2 \frac{A_s \xi_2^3}{N^4} \sim 10^{-6} \frac{\xi_2^3}{N^4} & \text{(metric),} \\ \frac{A_s}{N^4} \sim 10^{-9} \frac{1}{N^4} & \text{(Palatini).} \end{cases} \quad (4.20)$$

We see that near the attractor $\xi_2 \gg 1$ the metric formalism is stable against injection of λ_6 (unless $\xi_2 \gg 10^5$), while it is extremely sensitive to even tiny injection of λ_6 of order 10^{-16} in the Palatini formalism, regardless of ξ_2 .

As we increase $|\lambda_6|$ from zero, the inflationary prediction starts to deviate at around the value in the right-hand side of eq. (4.19). We note that this occurs when the higher dimensional operator $\lambda_6 \phi^6$ is still much smaller than the lower dimensional one $\lambda_4 \phi^4$. Indeed, by substituting the approximate values $\phi \simeq \sqrt{4N/3\xi_2}$ (metric) and $\sqrt{8N}$ (Palatini), the condition

$$|\lambda_6 \phi^6| \lesssim \lambda_4 \phi^4 \quad (4.21)$$

becomes

$$|\lambda_6| \lesssim \begin{cases} \frac{\lambda_4 \xi_2}{N} & \text{(metric),} \\ 10^{-1} \frac{\lambda_4}{N} & \text{(Palatini),} \end{cases} \quad (4.22)$$

which is well satisfied at the value in the right-hand side of eq. (4.19).

5 Summary and discussion

The Higgs(-like) inflation with the quartic coupling λ_4 and the non-minimal coupling ξ_2 is one of the best models from the viewpoint of cosmic microwave background observations. We have investigated the sensitivity of this model to higher dimensional operators in the Weyl rescaling factor ($\xi_4 \phi^4$) or in the potential ($\lambda_6 \phi^6$) both in the metric and Palatini formalisms.

We have found that, in the metric formalism, injection of order $|\xi_4| \sim 10^{-6}$ or $|\lambda_6| \sim 10^{-16}$ makes the value of n_s out of the observationally allowed region for $\xi_2 \lesssim 1$, while the inflationary predictions are relatively stable against λ_6 or ξ_4 for $\xi_2 \gg 1$ because of the existence of attractor. On the other hand, in the Palatini formalism, we have found that large $\xi_2 \gg 1$ does not help the stability: injection of order $|\xi_4| \sim 10^{-6}$ or $|\lambda_6| \sim 10^{-16}$ spoils the successful inflationary predictions regardless of the value of ξ_2 . We have also pointed out that these threshold values cannot be estimated from a naïve comparison between $\xi_2\phi^2$ and $\xi_4\phi^4$ or between $\lambda_4\phi^4$ and $\lambda_6\phi^6$ at the ϕ value corresponding to e -folding $N \sim 50 - 60$. Our study underscores the theoretical challenge in realizing inflationary models with the nonminimal coupling in the Palatini formalism.

Our result shows that large ξ_2 is necessary not only for the realization of inflation itself but also for the robustness of the prediction against the injection of the tiny higher dimensional operators in the metric formalism. This is interesting from theoretical point of view because it is unlikely to have such a large ξ_2 only in a single term in the field expansion in the low energy effective field theory. This may indicate a principle beyond.^{11,12}

It is known that the radiative corrections to λ_4 becomes important for $\lambda_4 \ll 1$, namely for the critical Higgs inflation. This will be studied in a separate publication.

A Equations

In this appendix we summarize expressions for the ϕ - χ relations, slow-roll parameters, and e -folding. We consider $\xi_2 > 0$, $\lambda_4 > 0$, and $\phi > 0$ for appendix A.1, while $\xi_2 > 0$, $\lambda_4 > 0$, and $\phi > 0$ for appendix A.2.

A.1 Correction to the nonminimal coupling

Metric formalism. ϕ - χ relation:

$$\frac{d\chi}{d\phi} = \frac{\sqrt{1 + \xi_2\phi^2 + \xi_4\phi^4 + 6(\xi_2\phi + 2\xi_4\phi^3)^2}}{1 + \xi_2\phi^2 + \xi_4\phi^4}. \quad (\text{A.1})$$

¹¹See e.g. ref. [64].

¹²Even in the vanilla model with only λ_4 and ξ_2 , it is theoretically intriguing why we have $\lambda_2 \ll \lambda_4$ and $1 \ll \xi_2$; the former is nothing but the hierarchy problem for the Higgs mass-squared.

Slow-roll parameters and e -folding:

$$\epsilon = \frac{8(1 - \xi_4 \phi^4)^2}{\phi^2 [1 + (\xi_2 + 6\xi_2^2) \phi^2 + (\xi_4 + 24\xi_2 \xi_4) \phi^4 + 24\xi_4^2 \phi^6]}, \quad (\text{A.2})$$

$$\eta = \frac{4 \left[\begin{aligned} &3 + (\xi_2 + 12\xi_2^2) \phi^2 + (-2\xi_2^2 - 12\xi_2^3 + 24\xi_2 \xi_4 - 11\xi_4) \phi^4 \\ &- (18\xi_2 \xi_4 + 144\xi_2^2 \xi_4) \phi^6 - (2\xi_2^2 \xi_4 + 12\xi_2^3 \xi_4 + 11\xi_4^2 + 384\xi_2 \xi_4^2) \phi^8 \\ &+ (\xi_2 \xi_4^2 - 12\xi_2^2 \xi_4^2 - 288\xi_4^3) \phi^{10} + (3\xi_4^3 + 72\xi_2 \xi_4^3) \phi^{12} + 96\xi_4^4 \phi^{14} \end{aligned} \right]}{\phi^2 [1 + (\xi_2 + 6\xi_2^2) \phi^2 + (\xi_4 + 24\xi_2 \xi_4) \phi^4 + 24\xi_4^2 \phi^6]^2}, \quad (\text{A.3})$$

$$N = \int d\phi \frac{\phi [1 + (\xi_2 + 6\xi_2^2) \phi^2 + (\xi_4 + 24\xi_2 \xi_4) \phi^4 + 24\xi_4^2 \phi^6]}{4(1 - \xi_4 \phi^4)(1 + \xi_2 \phi^2 + \xi_4 \phi^4)}$$

$$= \begin{cases} \begin{aligned} &\frac{1+6\xi_2}{8\sqrt{\xi_4}} \operatorname{arctanh} \left[\sqrt{\xi_4} \phi^2 \right] - \frac{3}{4} \ln \left[(1 - \xi_4 \phi^4) (1 + \xi_2 \phi^2 + \xi_4 \phi^4) \right] \\ &= \frac{1+6\xi_2}{16\sqrt{\xi_4}} \ln \left[\frac{1 + \sqrt{\xi_4} \phi^2}{1 - \sqrt{\xi_4} \phi^2} \right] - \frac{3}{4} \ln \left[(1 - \xi_4 \phi^4) (1 + \xi_2 \phi^2 + \xi_4 \phi^4) \right] \end{aligned} & (\xi_4 > 0 \ \& \ \phi < \xi_4^{1/4}), \\ \begin{aligned} &\frac{1+6\xi_2}{8\sqrt{-\xi_4}} \operatorname{arctan} \left[\sqrt{-\xi_4} \phi^2 \right] - \frac{3}{4} \ln \left[(1 - \xi_4 \phi^4) (1 + \xi_2 \phi^2 + \xi_4 \phi^4) \right] \\ &= \frac{1+6\xi_2}{16\sqrt{\xi_4}} \ln \left[\frac{1 + \sqrt{\xi_4} \phi^2}{1 - \sqrt{\xi_4} \phi^2} \right] - \frac{3}{4} \ln \left[(1 - \xi_4 \phi^4) (1 + \xi_2 \phi^2 + \xi_4 \phi^4) \right] \end{aligned} & (\xi_4 < 0). \end{cases} \quad (\text{A.4})$$

Palatini formalism. ϕ - χ relation:

$$\frac{d\chi}{d\phi} = \frac{1}{\sqrt{1 + \xi_2 \phi^2 + \xi_4 \phi^4}}, \quad (\text{A.5})$$

$$\chi = -i \sqrt{\frac{\xi_2 + \sqrt{\xi_2^2 - 4\xi_4}}{2\xi_4}} F \left(i \operatorname{arcsinh} \left[\sqrt{\frac{2\xi_4}{\xi_2 + \sqrt{\xi_2^2 - 4\xi_4}}} \phi \right] \middle| -1 + \frac{\xi_2(\xi_2 + \sqrt{\xi_2^2 - 4\xi_4})}{2\xi_4} \right), \quad (\text{A.6})$$

where $F(\varphi|m)$ is the elliptic integral of the first kind.

Slow-roll parameters and e -folding:

$$\epsilon = \frac{8(1 - \xi_4 \phi^4)^2}{\phi^2(1 + \xi_2 \phi^2 + \xi_4 \phi^4)}, \quad (\text{A.7})$$

$$N = \int d\phi \frac{\phi}{4(1 - \xi_4 \phi^4)}$$

$$= \begin{cases} \begin{aligned} &\frac{1}{8\sqrt{\xi_4}} \operatorname{arctanh} \left[\sqrt{\xi_4} \phi^2 \right] = \frac{1}{16\sqrt{\xi_4}} \ln \left[\frac{1 + \sqrt{\xi_4} \phi^2}{1 - \sqrt{\xi_4} \phi^2} \right] \end{aligned} & (\xi_4 > 0 \ \& \ \phi < \xi_4^{1/4}), \\ \begin{aligned} &\frac{1}{8\sqrt{-\xi_4}} \operatorname{arctan} \left[\sqrt{-\xi_4} \phi^2 \right] = \frac{1}{16\sqrt{\xi_4}} \ln \left[\frac{1 + \sqrt{\xi_4} \phi^2}{1 - \sqrt{\xi_4} \phi^2} \right] \end{aligned} & (\xi_4 < 0). \end{cases} \quad (\text{A.9})$$

A.2 Correction to the potential

Metric formalism. ϕ - χ relation:

$$\frac{d\chi}{d\phi} = \frac{\sqrt{1 + \xi_2(1 + 6\xi_2)\phi^2}}{1 + \xi_2\phi^2}, \quad (\text{A.10})$$

$$\begin{aligned} \chi &= \sqrt{\frac{1 + 6\xi_2}{\xi_2}} \operatorname{arcsinh} \left[\sqrt{\xi_2(1 + 6\xi_2)}\phi \right] - \sqrt{6} \operatorname{arctanh} \left[\frac{\sqrt{6}\xi_2\phi}{\sqrt{1 + \xi_2(1 + 6\xi_2)\phi^2}} \right] \\ &= \sqrt{\frac{1 + 6\xi_2}{\xi_2}} \ln \left[\sqrt{\xi_2(1 + 6\xi_2)}\phi + \sqrt{1 + \xi_2(1 + 6\xi_2)\phi^2} \right] \\ &\quad - \frac{\sqrt{6}}{2} \ln \left[\frac{\sqrt{1 + \xi_2(1 + 6\xi_2)\phi^2} + \sqrt{6}\xi_2\phi}{\sqrt{1 + \xi_2(1 + 6\xi_2)\phi^2} - \sqrt{6}\xi_2\phi} \right]. \end{aligned} \quad (\text{A.11})$$

Slow-roll parameters and e -folding:

$$\epsilon = \frac{2(2 + 3\lambda_{64}\phi^2 + \xi_2\lambda_{64}\phi^4)^2}{\phi^2 [1 + (\xi_2 + 6\xi_2^2)\phi^2] (1 + \lambda_{64}\phi^2)^2}, \quad (\text{A.12})$$

$$\eta = \frac{2 \left[6 + (2\xi_2 + 24\xi_2^2 + 15\lambda_{64})\phi^2 + (-4\xi_2^2 - 24\xi_2^3 + 2\xi_2\lambda_{64} + 72\xi_2^2\lambda_{64})\phi^4 \right]}{\phi^2 [1 + (\xi_2 + 6\xi_2^2)\phi^2]^2 (1 + \lambda_{64}\phi^2)}, \quad (\text{A.13})$$

$$N = \int d\phi \frac{\phi [1 + (\xi_2 + 6\xi_2^2)\phi^2] (1 + \lambda_{64}\phi^2)}{2(1 + \xi_2\phi^2)(2 + 3\lambda_{64}\phi^2 + \xi_2\lambda_{64}\phi^4)}, \quad (\text{A.14})$$

where we use

$$\lambda_{64} \equiv \lambda_6/\lambda_4 \quad (\text{A.15})$$

for abbreviation.

Palatini formalism. ϕ - χ relation:

$$\frac{d\chi}{d\phi} = \frac{1}{\sqrt{1 + \xi_2\phi^2}}, \quad (\text{A.16})$$

$$\chi = \frac{1}{\sqrt{\xi_2}} \operatorname{arcsinh} \left[\sqrt{\xi_2}\phi \right] = \frac{1}{\sqrt{\xi_2}} \ln \left[\sqrt{\xi_2}\phi + \sqrt{1 + \xi_2\phi^2} \right]. \quad (\text{A.17})$$

Slow-roll parameters and e -folding:

$$\epsilon = \frac{2(2 + 3\lambda_{64}\phi^2 + \xi_2\lambda_{64}\phi^4)^2}{\phi^2(1 + \xi_2\phi^2)(1 + \lambda_{64}\phi^2)^2}, \quad (\text{A.18})$$

$$\eta = \frac{2 [6 + (-4\xi_2 + 15\lambda_{64})\phi^2 + 7\xi_2\lambda_{64}\phi^4 + 2\xi_2^2\lambda_{64}\phi^6]}{\phi^2(1 + \xi_2\phi^2)(1 + \lambda_{64}\phi^2)}, \quad (\text{A.19})$$

$$N = \int d\phi \frac{\phi(1 + \lambda_{64}\phi^2)}{2(2 + 3\lambda_{64}\phi^2 + \xi_2\lambda_{64}\phi^4)}. \quad (\text{A.20})$$

B Difference from $f(R)$ Palatini theories

It has been pointed out in ref. [65] that $f(R)$ theories in Palatini formalism are equivalent to the strong coupling limit of the Brans-Dicke theory. This can be seen by rewriting the $f(R)$ action as

$$S = \int d^4x \sqrt{-g} f(R) \quad \rightarrow \quad S = \int d^4x \sqrt{-g} [f(\chi) + f'(\chi)(R - \chi)]. \quad (\text{B.1})$$

This action is equivalent to the $w \rightarrow 0$ limit of the Brans-Dicke theory

$$S = \int d^4x \sqrt{-g} \left[\Phi R - \frac{w}{\Phi} g^{\mu\nu} \nabla_\mu \Phi \nabla_\nu \Phi - V(\Phi) \right], \quad (\text{B.2})$$

with the identification $f'(\chi) = \Phi$ and $V(\Phi) = \chi f'(\chi) - f(\chi)$. The point here is that there is no kinetic term in the auxiliary field χ . In the Palatini formalism, no additional kinetic term of χ appears when moving to the Einstein frame. The canonical field becomes $\Phi_{\text{canonical}} \sim \sqrt{w} \ln \Phi$ in that frame and causes strong coupling problems in the $w \rightarrow 0$ limit. This argument does not directly apply to our setup, since our starting action (2.1) has a kinetic term in the original frame.

Another issue mentioned in ref. [65] is about picking up a particular theory from infinitely many possibilities. In this reference, the relation between the connection and metric is imposed explicitly by a Lagrange multiplier. If this multiplier is such that the connection becomes the Levi-Civita type in a frame different from the original one (e.g. the Einstein frame), a question would arise why a multiplier that gives the Levi-Civita connection in this specific frame is chosen despite infinitely many other possibilities. However, in our setup we regard the connection as a variable which we take variation with. Then the connection is uniquely determined by the Levi-Civita form made from the Einstein-frame metric as a result of the variation principle, and therefore no such an ambiguity arises.
